3 **ABSTRACT**  
4  
5

6 Recently, the prevention of cardiovascular events has become one of the most  
7  
8  
9 important aims of diabetes care. Peroxisome proliferator-activated receptor  
10  
11  
12 (PPAR) agonists have been reported to have vascular protective effects. Here,  
13  
14  
15 we examined whether pemafibrate, a selective PPAR alpha agonist, attenuated  
16  
17  
18 neointima formation after vascular injury and vascular smooth muscle cell  
19  
20  
21 (VSMC) proliferation. We performed endothelial denudation injury in mice  
22  
23  
24 treated with a high-fat diet (HFD) or normal chow. Orally administered  
25  
26  
27 pemafibrate significantly attenuated neointima formation after vascular injury in  
28  
29  
30 HFD and normal chow mice. Interestingly, pemafibrate increased the serum  
31  
32  
33 fibroblast growth factor 21 concentration and decreased serum insulin  
34  
35  
36 concentrations in HFD mice. In addition, body weight was slightly but  
37  
38  
39 significantly decreased by pemafibrate in HFD mice. Pemafibrate, but not  
40  
41  
42 bezafibrate, attenuated VSMC proliferation *in vitro*. The knockdown of PPAR  
43  
44  
45 alpha abolished the anti-VSMC proliferation effect of pemafibrate. BrdU assay  
46  
47  
48 results revealed that pemafibrate dose-dependently inhibited DNA synthesis in  
49  
50  
51 VSMCs. Flow cytometry analysis demonstrated that G1-to-S phase cell cycle  
52  
53  
54 transition was significantly inhibited by pemafibrate. Pemafibrate attenuated  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 serum-induced cyclin D1 expression in VSMCs. However, apoptosis was not  
4  
5  
6 induced by pemafibrate as assessed by the TUNEL assay. Similar to the *in vitro*  
7  
8  
9 data, VSMC proliferation was also decreased by pemafibrate in mice. These  
10  
11  
12 data suggest that pemafibrate attenuates neointima formation after vascular  
13  
14  
15 injury and VSMC proliferation by inhibiting cell cycle progression.

6 **Introduction**  
7

8  
9 Cardiovascular events (CVEs) are one of the most critical vascular complications  
10  
11 in patients with type 2 diabetes mellitus (T2DM). Accordingly, large scale clinical  
12  
13 trials investigating CVE reduction using novel anti-diabetic agents have provided  
14  
15 profound results for diabetes care [1]. In addition to primary CVEs, restenosis  
16  
17 after coronary angioplasty remains a critical problem for patients with T2DM [2].  
18  
19 Guidewire-induced endothelial denudation injury has been established as an  
20  
21 experimental mouse model for restenosis and vascular thickening after coronary  
22  
23 angioplasty or vascular injury [3]. Importantly, the pathogenesis of vascular  
24  
25 thickening caused by wire injury reflects vascular smooth muscle cell (VSMC)  
26  
27 proliferation after the phenotype switching of VSMCs [4]. Previously, we  
28  
29 demonstrated that anti-diabetic agents, including glucagon-like peptide-1 (GLP-  
30  
31 1) receptor agonist [5], dipeptidyl peptidase-4 (DPP-4) inhibitor [6], and sodium-  
32  
33 glucose cotransporter 2 (SGLT2) inhibitor [7], attenuated neointima formation  
34  
35 after vascular injury and VSMC proliferation. VSMC proliferation and phenotype  
36  
37 switching are precisely regulated by nuclear receptors. We previously reported  
38  
39 that nuclear orphan receptor NR4A neuron-derived orphan receptor1 (NOR1)  
40  
41  
42  
43

64  
65

1  
2  
3 plays an important role in VSMC proliferation and neointima formation after  
4  
5  
6 vascular injury [8, 9]. Among nuclear orphan receptors, drugs targeting  
7  
8  
9 peroxisome proliferator-activated receptor (PPAR) alpha are clinically available  
10  
11  
12 for the treatment of hypertriglyceridemia, which is a residual risk for CVEs in  
13  
14  
15 patients with obesity and T2DM [10]. Pemafibrate (K-877) is a PPAR alpha  
16  
17  
18 agonist with a highly selective binding affinity to PPAR alpha compared with other  
19  
20  
21 agonists [11]. In the present study, we examined whether pemafibrate attenuated  
22  
23  
24 neointima formation in mice fed normal chow and a high-fat diet (HFD) and VSMC  
25  
26  
27 proliferation *in vitro*.

## 35 **Materials and Methods**

### 36 37 38 **Animals**

39  
40  
41 All study protocol and experiments were reviewed and approved by the Animal  
42  
43  
44 Care and Use Committee of Fukuoka University (Approval number 1705050).  
45  
46  
47 The study conformed to the *Guide for the Care and Use of Laboratory Animals*  
48  
49  
50 published by the US National Institutes of Health (NIH Publication No. 85-23,  
51  
52  
53 revised 1996). Four-week-old male C57BL/6 mice were purchased from Oriental  
54  
55  
56 Yeast (Tokyo, Japan). All mice were housed as previously described [7]. Water  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 was available *ad libitum*. Mice were divided into the following treatment groups:  
4  
5  
6 normal chow-control (n = 10), normal chow-pemafibrate (n = 10), HFD-control (n  
7  
8 =10), and HFD-pemafibrate (n = 10). Pemafibrate was kindly provided by the  
9  
10 Kowa Company, Ltd. (Tokyo, Japan). Control mice were fed normal chow (22.6%  
11  
12 protein, 53.8% carbohydrate, 5.6% fat, 6.6% minerals, a vitamin mixture, and  
13  
14 3.3% fiber; 356 kcal/100 g) or HFD (20% protein, 20% carbohydrate, 60.0% fat,  
15  
16 D12492, Research Diet) with methyl cellulose (vehicle control) or pemafibrate, at  
17  
18 6 weeks of age. Pemafibrate was dissolved in methyl cellulose, diluted with water,  
19  
20 and administered to the relevant experimental groups (0.1 mg/kg/day). The  
21  
22 animal room had a 12-h light/dark cycle, constant temperature (22 ± 1°C), and  
23  
24 relative humidity of 55 ± 5% throughout the experimental period. Endothelial  
25  
26 denudation injuries were induced in the left femoral artery at 8 weeks of age,  
27  
28 followed by the evaluation of neointima formation at 12 weeks of age.

45  
46

### 47 **Guidewire-induced endothelial denudation injury**

48  
49 A femoral artery endothelial denudation injury was established in mice at 6 weeks  
50  
51 of age as described previously [5-7, 9]. Mice were euthanized at 12 weeks of age,  
52  
53  
54  
55  
56  
57 and femoral arteries were isolated for analysis.  
58

1  
2  
3  
4  
5  
6 **Tissue preparation and morphometry**  
7

8  
9 Following sacrifice, mice were perfused via a cannula in the left ventricle with  
10 phosphate-buffered saline for 5 min, followed by 4% paraformaldehyde for 30 min  
11  
12 at 100 cm H<sub>2</sub>O. The femoral arteries were embedded in paraffin, cut into 5- $\mu$ m  
13  
14 sections, and prepared for Elastica van Gieson staining. Serial sections were  
15  
16 evaluated using an Elastica van Gieson stain kit (HT25A-1KT; Sigma-Aldrich,  
17  
18 Tokyo, Japan) to visualize the internal elastic lamina as described previously [5-  
19  
20 7]. Specimens were viewed under a BZ9000 microscope (Keyence, Tokyo,  
21  
22 Japan). The intimal and medial areas were measured by computerized  
23  
24 morphometry using a BZ-II analyzer (Keyence). Intimal hyperplasia was defined  
25  
26 as described previously [5-7]. The medial area represents the area between  
27  
28 external and internal elastic laminae. The intima-to-media ratio was calculated as  
29  
30 the intimal area divided by the media area as described previously [5-7].

47  
48  
49  
50

51 **Immunohistochemistry**  
52

53  
54 Paraffin sections were incubated with a Cy-3-conjugated  $\alpha$ -smooth muscle actin  
55  
56 antibody (C6198, Sigma Aldrich). Serial sections were incubated with an anti-  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 PCNA antibody (#sc-56, Santa Cruz) and subsequently incubated with an Alexa  
4  
5  
6 Fluor 546 goat anti-mouse IgG secondary antibody (#A-11030, Thermo Fisher  
7  
8  
9 Scientific). Sections were counterstained with DAPI and visualized by confocal  
10  
11  
12  
13 microscopy.

### 14 15 16 17 18 19 **Laboratory data**

20  
21  
22 Blood samples were collected at euthanasia. The plasma glucose concentration  
23  
24  
25 was measured by a Glutest Neo Super device (Sanwa Chemical Co.,  
26  
27  
28 Kanagawa, Japan). Insulin concentrations in mouse serum were measured  
29  
30  
31 using the Ultra Sensitive Mouse Insulin ELISA Kit (Morinaga Institute of  
32  
33  
34 Biological Science, Inc. Kanagawa, Japan) according to the manufacturer's  
35  
36  
37 protocol. Fibroblast growth factor 21 (FGF21) concentrations in mouse serum  
38  
39  
40 were measured using an FGF21 Mouse/Rat ELISA Kit (RD291108200R,  
41  
42  
43 BioVendor, Karasek, Czech Republic) according to the manufacturer's protocol.  
44  
45  
46 Lipid profiles were determined by a local laboratory (Skylight Biotech, Tokyo,  
47  
48  
49  
50  
51 Japan).

### 52 53 54 55 56 57 **Cell culture**

1  
2  
3 Rat aortic smooth muscle cells (RASMCs) were purchased from Lonza (Allendale,  
4  
5  
6 NJ, USA) and maintained in DMEM/Ham's F-12 (042-30555, Wako, Osaka,  
7  
8  
9 Japan) supplemented with 10% fetal bovine serum (FBS) and 1%  
10  
11  
12 penicillin/streptomycin. Passages three and six cells were used between for  
13  
14  
15  
16 experiments, and individual experiments were repeated at least three times with  
17  
18  
19 different cell preparations.  
20  
21  
22  
23  
24

### 25 **Proliferation assay**

26  
27  
28 Cell proliferation assays were performed as described previously [6, 7] with minor  
29  
30  
31 modifications. Briefly, RASMCs were seeded in 12-well tissue culture plates and  
32  
33  
34 maintained in complete media with or without 1–1000 nM pemafibrate or 100–  
35  
36  
37 500  $\mu$ M bezafibrate (#022-16091, Fujifilm Wako Chemicals, Osaka, Japan). Cell  
38  
39  
40 proliferation was analyzed from 0 to 72 h by cell counting using a hemocytometer.  
41  
42  
43  
44  
45  
46  
47

### 48 **Small interfering RNA (siRNA) knockdown of *PPAR alpha* expression and** 49 50 51 **cell proliferation assay**

52  
53  
54 To knockdown *PPAR alpha*, we used an order-designed siRNA (Theoria  
55  
56  
57 Science, Tokyo, Japan) targeting rat *PPAR alpha*. We used negative control  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 siRNA from the same company, as a control. For transfection, RASMCs were  
4  
5  
6 plated at  $2 \times 10^5$  cells/well in six-well plates and transfected with 10 nmol/l of  
7  
8  
9 siRNA targeting *PPAR alpha* or negative control siRNA using Lipofectamine  
10  
11  
12 RNAiMAX (Invitrogen, Carlsbad, CA, USA). Seventy-two hours after  
13  
14  
15  
16 transfection, cells were subjected to the cell proliferation assay. Briefly, cells  
17  
18  
19 were detached and re-plated in 12-well tissue culture plates in complete media  
20  
21  
22 with or without 100 nM pemafibrate, or 100  $\mu$ M bezafibrate. At 0–72 h after  
23  
24  
25 treatment, cells were collected and counted using a hemocytometer. The siRNA  
26  
27  
28 knockdown efficiency was confirmed by RT-PCR.  
29  
30

### 31 32 33 34 35 **Bromodeoxyuridine (BrdU) assay** 36

37  
38 For evaluation of the cell proliferation of RASMCs, a BrdU incorporation assay  
39  
40  
41 was demonstrated using a Cell Proliferation ELISA kit (1647229; Roche Applied  
42  
43  
44 Science, Mannheim, Germany). RASMCs were cultured at 4000 cells/well in 96-  
45  
46  
47 well culture plates in complete media (n = 5). At 60%–70% confluence, cells  
48  
49  
50  
51 were maintained in serum-free media for 24 h. At 12 h before serum stimulation,  
52  
53  
54 cells were treated with 0–1000 nM pemafibrate, or 0-1000 $\mu$ M bezafibrate and  
55  
56  
57 subsequently stimulated with 10% FBS for 48 h. A BrdU (10  $\mu$ M) solution was  
58  
59  
60

1  
2  
3 added during the last 2 h of incubation. Subsequently, the cells were dried and  
4  
5  
6 fixed, and cellular DNA was denatured with FixDenat solution (Roche Applied  
7  
8  
9 Science) for 30 min at room temperature. A peroxidase-conjugated mouse anti-  
10  
11  
12 BrdU monoclonal antibody (Roche Applied Science) was added to the culture  
13  
14  
15 plates, followed by incubation for 90 min at room temperature. Finally, a  
16  
17  
18 tetramethylbenzidine substrate was applied for 15 min at room temperature,  
19  
20  
21 and the absorbance of samples was measured using a microplate reader at  
22  
23  
24 450–620 nm. Mean data were expressed as a ratio of the control (untreated)  
25  
26  
27  
28  
29 cell proliferation.  
30

### 31 32 33 34 35 **Cell cycle analysis using flow cytometry** 36

37  
38 RASMCs were seeded in 60-mm dishes at a density of  $1 \times 10^5$  cells/ml. After  
39  
40  
41 growth to 60%–70% confluence and serum deprivation for 24 h, the cells were  
42  
43  
44 pretreated with 100 nM pemaibrate or dimethyl sulfoxide (DMSO) for 12 h and  
45  
46  
47 then stimulated with FBS for 24 h. Cell cycle analysis was performed using a  
48  
49  
50

### 8 9 **Apoptosis assay**

10  
11  
12 To label the nuclei of cells going into apoptosis,  $1 \times 10^5$  RSMCs were plated on  
13  
14 glass coverslips in Lab-Tek Chamber Slides (177380; Nunc, Thermo Scientific,  
15  
16 Waltham, MA, USA) and maintained in complete media with 100 nM  
17  
18  
19 pemafibrate for 48 h. The cells were fixed in 4% paraformaldehyde for 25 min.  
20  
21  
22

23  
24  
25 Terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling  
26  
27  
28 (TUNEL) was demonstrated using the DeadEnd Fluorometric TUNEL System  
29  
30  
31 (Promega, Madison, WI, USA) in accordance with the manufacturer's protocol.  
32  
33

34  
35 Cells treated with 1 U/100  $\mu$ l RQ1 RNase-Free DNase (M6101; Promega) for 10  
36  
37  
38 min were used as a positive control.  
39  
40  
41

### 42 43 44 **Western blot analysis**

45  
46  
47 Western blotting was performed as described previously [13]. The following  
48  
49  
50 primary antibodies were used: Cyclin D1 (#2978; Cell Signaling Technology,  
51  
52  
53 Danvers, MA, USA) and  $\beta$ -actin (sc-47778; Santa Cruz Biotechnology, Santa  
54  
55  
56 Cruz, CA, USA).  
57  
58

1  
2  
3  
4  
5  
6 **Reverse transcription (RT) and quantitative real-time PCR**  
7

8  
9 RT and quantitative real-time PCR were performed as described previously  
10  
11 [13]. Each sample was analyzed in triplicate and normalized against  
12  
13 *hypoxanthine phosphoribosyltransferase (HPRT)* mRNA expression. The primer  
14  
15  
16 sequences were as follows: rat *HPRT*, 5'-AGGACCTCTCGAAGTGTTGG-3'  
17  
18  
19 (forward), 5'-GATTCAACTTGCCGCTGTCT-3' (reverse); rat *Ppar alpha*, 5'-  
20  
21  
22 TGGCAATGCACTGAACATCG-3' (forward), 5'-GCAACAATCGCCTTTTGTC-3'  
23  
24  
25 (reverse); and rat *Ccnd1*, 5'-ATGCTGGTTTTTGCCTGGTG-3' (forward), 5'-  
26  
27  
28 AGCTAGCTGACCAAAGTGC-3' (reverse).  
29  
30  
31  
32  
33  
34  
35  
36  
37

38 **Statistical analysis**  
39

40  
41 Results are expressed as the mean  $\pm$  SEM. All statistical analyses were  
42  
43 performed using GraphPad Prism software (version 7.0; GraphPad Software, La  
44  
45 Jolla, CA, USA). In experiments comparing multiple groups, differences were  
46  
47 analyzed by an unpaired *t*-test or one-way or two-way ANOVA, followed by  
48  
49 Sidak's *post-hoc* test as appropriate.  $P < 0.05$  was considered statistically  
50  
51 significant.

12  
13

14  
15  
16 To evaluate neointima formation after vascular injury by endothelial denudation,  
17  
18 we performed elastic staining of the left femoral artery with injury extracted from  
19  
20 mice maintained on a normal chow diet (Figure 1A). In the control vessel,  
21  
22 obviously thickened neointima formation was observed. However, a much  
23  
24 smaller neointima was observed in the vessels from pemafibrate-treated mice.  
25  
26 Intima area and intima/media ratio measurements revealed that pemafibrate  
27  
28 significantly reduced the intima/media ratio (Figure 1B). In the vascular injury of  
29  
30 mice maintained on a HFD, pemafibrate reduced neointima formation (Figure 1C)  
31  
32 and significantly reduced the intima/media ratio (Figure 1D).  
33

47 **Pemafibrate attenuates VSMC proliferation in mice fed both normal chow**  
48  
49 **and a HFD**  
50  
51

52  
53  
54 To confirm that pemafibrate attenuated neointima formation by inhibiting VSMC  
55  
56 proliferation, we stained and counted VSMC numbers localized in the neointima  
57  
58  
59  
60

1  
2  
3 and media. As shown in Figure 2A, the neointima and media were occupied by  
4  
5  
6 VSMCs, and cell counting revealed that pemafibrate significantly attenuated  
7  
8  
9 VSMC numbers in the neointima and the intima/media ratio (Figure 2B). The  
10  
11  
12 same result was observed in HFD mice (Figure 2C, D). Laboratory data of mice  
13  
14  
15 are shown in Table 1. Compared with the normal chow group, body weight, serum  
16  
17  
18 insulin levels, LDL cholesterol, and HDL cholesterol were significantly increased,  
19  
20  
21 and VLDL cholesterol was significantly decreased in HFD mice. In HFD mice, the  
22  
23  
24 body weight and serum insulin level were significantly decreased by pemafibrate.  
25  
26  
27 Triglyceride and VLDL cholesterol were significantly decreased by pemafibrate in  
28  
29  
30 both groups. Interestingly, FGF21 was only detected in diabetic HFD mice and  
31  
32  
33 was significantly increased by pemafibrate.

#### 41 **Pemafibrate attenuates VSMC proliferation *in vitro***

42  
43  
44 To confirm that pemafibrate directly attenuated VSMC proliferation, we performed  
45  
46  
47 *in vitro* experiments using RASMCs. As shown in Figure 3A, pemafibrate  
48  
49  
50 significantly attenuated VSMC proliferation in a dose-dependent manner.  
51  
52  
53 However, the widely-used clinically available PPAR alpha agonist bezafibrate did  
54  
55  
56 not attenuate RASMC proliferation, and long-term incubation with bezafibrate  
57  
58  
59  
60

1  
2  
3 increased RASMC numbers, whereas pemafibrate decreased RASMC numbers  
4  
5  
6 (Figure 3B). The BrdU assay results revealed that pemafibrate but not bezafibrate  
7  
8  
9 attenuated RASMC proliferation by inhibiting DNA duplication dose-dependently  
10  
11  
12  
13 (Figure 3C, D).  
14  
15  
16  
17  
18

### 19 **Pemafibrate attenuates VSMC proliferation via PPAR alpha activation**

20  
21  
22 To confirm that pemafibrate attenuated RASMC proliferation via PPAR alpha  
23  
24  
25 activation, we knocked down PPAR alpha in RASMCs. As shown in Figure 4A, a  
26  
27  
28 significant reduction in cell proliferation induced by pemafibrate was observed in  
29  
30  
31 RASMCs treated with control siRNA, but the anti-proliferative effect of  
32  
33  
34 pemafibrate was completely abolished by knocking down PPAR alpha. However,  
35  
36  
37 bezafibrate did not decrease the number of RASCs treated by both the control  
38  
39  
40 and PPAR alpha siRNA (Figure 4B). To confirm the knockdown efficiency of  
41  
42  
43 PPAR alpha, we performed quantitative RT-PCR of *PPARalpha*. As shown in  
44  
45  
46 Figure 4C, *PPARalpha* expression was almost completely abolished in cells  
47  
48  
49 transfected with siRNA targeting *PPARalpha*.  
50

1  
2  
3 **Pemafibrate attenuates VSMC proliferation by inhibiting cyclin D1**  
4  
5  
6 **expression and cell cycle progression but does not induce apoptosis**  
7  
8

9  
10 VSMC proliferation is mainly regulated by cell cycle progression, and therefore  
11  
12 we performed flow cytometry analysis to determine cell cycle distribution. As  
13  
14  
15 shown in Figure 5A, pemafibrate attenuated the G0/G1-to-S phase transition  
16  
17 induced by serum stimulation in RASMCs. However, pemafibrate did not induce  
18  
19 apoptosis in RASMCs (Figure 5B). Cyclin D1 is an important cell cycle regulator  
20  
21  
22 in the G0/G1-to-S phase transition and is a target gene of PPAR alpha required  
23  
24  
25 for VSMC proliferation [14]. Next, we examined cyclin D1 expression. As shown  
26  
27  
28 in Figure 5C, cyclin D1 protein expression induced by serum stimulation was  
29  
30  
31 significantly decreased by pemafibrate. In addition, *cyclin D1* gene expression  
32  
33  
34 was significantly decreased by pemafibrate (Figure 5D).  
35  
36

44 **Pemafibrate attenuates VSMC proliferation *in vivo***  
45  
46

47  
48 To confirm the mechanism by which pemafibrate attenuates neointima formation  
49  
50  
51 and connect the data obtained from *in vitro* and *in vivo* experiments, we  
52  
53  
54 performed the immunohistochemistry of proliferation cell nuclear antigen (PCNA)  
55  
56  
57 using injured mice vessels. As shown in Figure 6, the proportion of PCNA-positive  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 proliferating VSMCs was significantly decreased by pemafibrate in both mice fed  
4  
5  
6 normal chow (Figure 6A, B) and a HFD (Figure 6C, D).  
7  
8  
9

## 10 11 12 **Discussion**

13  
14  
15  
16 Currently, the aim of treating patients with diabetes includes glucose-lowering  
17  
18 and decreasing CVEs [1]. In addition to anti-diabetic agents, the vascular  
19  
20 protective effects of lipid-lowering drugs, such as statins [15] and  
21  
22 eicosapentaenoic acid [16], were demonstrated in patients with T2DM. However,  
23  
24 the vascular protective effect of fibrates is not well understood either in the clinic  
25  
26 or basic science research. In the present study, we investigated whether  
27  
28 pemafibrate attenuated neointima formation in both mice fed normal chow and a  
29  
30 HFD. Cell counting revealed that the inhibition of neointima formation by  
31  
32 pemafibrate was related to the attenuation of VSMC proliferation. In HFD mice,  
33  
34 body weight and serum insulin levels were significantly decreased by pemafibrate,  
35  
36 suggesting pemafibrate improved insulin resistance and hyperinsulinemia.  
37  
38 Because insulin is a proliferation stimulus for VSMCs, the reduction in serum  
39  
40 insulin levels may be a mechanism by which pemafibrate decreased neointima  
41  
42 formation after vascular injury. However, an insulin-independent mechanism may  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 also exist because pemafibrate decreased neointima formation in non-diabetic  
4  
5  
6 and non-hyperinsulinemic mice on a normal chow diet. Interestingly, serum  
7  
8  
9 FGF21 levels were increased by pemafibrate in HFD mice. In a previous study,  
10  
11  
12 pemafibrate increased serum FGF21 levels in humans [18] and *FGF21* gene  
13  
14  
15 expression in mice [19]. In addition, pemafibrate attenuated neovascularization  
16  
17  
18 by increasing FGF21 [20]. However, FGF21 was not part of the mechanism by  
19  
20  
21 which pemafibrate attenuated neointima formation because we did not observe  
22  
23  
24 an anti-proliferative effect of FGF21 in VSMC *in vitro* experiments (data not  
25  
26  
27 shown). Further studies of the vascular protective effect of FGF21 induced by  
28  
29  
30 pemafibrate are required. In the previous report, Lee et al. reported that the PPAR  
31  
32  
33 alpha agonist fenofibrate also reduced neointima formation after vascular injury  
34  
35  
36 [21]. In this report, they observed a 30%–40% reduction in neointima formation  
37  
38  
39 after vascular injury, which was greater than our present data. However, the  
40  
41  
42 animal model and drug dose were substantially different. Therefore, further  
43  
44  
45 experiments directly comparing the reduction in neointima formation by PPAR  
46  
47  
48 alpha agonists are required.  
49  
50  
51

52  
53  
54 We also observed that pemafibrate attenuated VSMC proliferation *in vitro*,  
55  
56  
57 suggesting it directly attenuates VSMC proliferation independent of body weight  
58  
59  
60

1  
2  
3 and serum insulin level reduction. Interestingly, another PPAR alpha agonist,  
4  
5  
6 bezafibrate, which is clinically available as a drug for hypertriglyceridemia, did not  
7  
8  
9 inhibit VSMC proliferation even at a higher dose compared with pemafibrate. This  
10  
11  
12 suggests that the vascular protective effect of pemafibrate is not a class effect of  
13  
14  
15 fibrates but a specific drug effect of pemafibrate. This might be a feature of the  
16  
17  
18 selective PPAR alpha modulator [19]. Furthermore, knocking down PPAR alpha  
19  
20  
21 confirmed that the molecular target of pemafibrate that attenuated VSMC  
22  
23  
24 proliferation was PPAR alpha. In the BrdU assay, >10 nM pemafibrate decreased  
25  
26  
27 DNA synthesis; however, the serum concentration of pemafibrate administered  
28  
29  
30 orally at a clinical dose is almost 3 nM (unpublished data by Kowa Company Ltd.),  
31  
32  
33 suggesting that our data might mirror clinical conditions. Compatible with our  
34  
35  
36 previous reports regarding the inhibition of VSMC proliferation [9, 22],  
37  
38  
39 pemafibrate attenuated VSMC proliferation by inhibiting G0/G1-to-S phase cell  
40  
41  
42 cycle transition. Furthermore, cyclin D was the target molecule and gene, similar  
43  
44  
45 to a previous report [14]. However, other reports suggested that the target of  
46  
47  
48 PPAR alpha in VSMCs was p16INKa [23] and that p16 and cyclin D1 correlated  
49  
50  
51 with VSMC biology [24]. Further experiments to elucidate the precise molecular  
52  
53  
54 mechanism by which pemafibrate attenuates VSMC proliferation are required. In  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 the present study, we observed that pemafibrate attenuated VSMC proliferation  
4  
5  
6 both *in vitro* and *in vivo*. These data suggested that the anti-proliferative effect  
7  
8  
9 could be a confirmative direct mechanism by which pemafibrate attenuates  
10  
11  
12 vascular diseases. There are some limitations to our VSMC experiments. We  
13  
14  
15 used only VSMC cultures because we focused on VSMC proliferation. However,  
16  
17  
18 the micro-artery does not include VSMCs. Accordingly, our experiments  
19  
20  
21 demonstrated the pathophysiology of the muscular artery. In addition, we cultured  
22  
23  
24 VSMCs in high glucose medium following the supplier's instruction and cell  
25  
26  
27 culture protocol. This did not precisely reproduce normal glucose tolerance  
28  
29  
30 conditions, and single-cell culture does not enable cell-cell interactions. Therefore,  
31  
32  
33 further elucidation is required. In addition to our study, previous reports  
34  
35  
36 demonstrated a vascular protective effect of pemafibrate using other vascular  
37  
38  
39 cells, such as endothelial cells [25] and macrophages [26], suggesting that this  
40  
41  
42 effect of pemafibrate is not cell-type specific.  
43  
44  
45

46  
47  
48 In a previously reported clinical study, fenofibrate did not reduce CVEs in patients  
49  
50  
51 with T2DM and metabolic syndrome [27]. In addition, it was reported that  
52  
53  
54 fenofibrate was not associated with beneficial changes in carotid intima-media  
55  
56  
57 thickness in patients with T2DM [28]. Unfortunately, these data suggested that  
58  
59  
60

1  
2  
3 the reduction in hypertriglyceridemia induced by fibrate did not exhibit a vascular  
4  
5  
6 protective effect, even if hypertriglyceridemia is the most critical risk factor for  
7  
8  
9 CVEs in Japanese patients with T2DM [29]. However, a clinical study  
10  
11  
12 investigating pemafibrate is currently ongoing [30]. Hopefully, we will observe  
13  
14  
15  
16 CVE reduction by pemafibrate in patients with T2DM.

17  
18  
19 In conclusion, we report that the PPAR alpha agonist pemafibrate attenuates  
20  
21  
22 neointima formation in both mice fed by normal chow and HFD, and reduced  
23  
24  
25 VSMC proliferation by inhibiting cyclin D1 expression and cell cycle progression.  
26  
27

## 38 **Figure legends**

39  
40  
41 **Figure 1. Pemafibrate attenuates neointima formation after vascular injury**  
42  
43  
44 **in mice with or without a HFD.**

45  
46  
47 Endothelial denudation injuries were induced in the left femoral artery of mice  
48  
49  
50 maintained with normal chow (A, B) or a HFD (C, D). (A, C) The left femoral artery  
51  
52  
53 with injury was evaluated by Elastica van Gieson staining to visualize the internal  
54  
55  
56 elastic lamina (magnification,  $\times 200$ ). (B, D) Intima areas and the intima/media  
57  
58  
59  
60

1  
2  
3 ratio (I/M ratio) were calculated for each group. Data are the mean  $\pm$  SEM.

4  
5  
6 Unpaired *t*-test was performed to calculate statistical significance ( $*P < 0.05$  vs  
7  
8  
9 control).

10  
11  
12  
13  
14  
15  
16 **Figure 2. Pemaifibrate attenuates VSMC proliferation and migration after**  
17  
18  
19 **vascular injury in mice with or without a HFD.**

20  
21  
22 Endothelial denudation injuries were induced in the left femoral artery of mice  
23  
24  
25 maintained on normal chow (A, B) or a HFD (C, D). (A, C) Sections were  
26  
27  
28 subjected to immunohistochemistry for  $\alpha$ -SMA (red) and counterstained with  
29  
30  
31 DAPI to visualize nuclei (blue). Magnification, 630 $\times$ . (B, D) Total DAPI count of  
32  
33  
34 the intima and the intima/media ratio (I/M ratio) were calculated for each group.  
35  
36  
37 Data are the mean  $\pm$  SEM. Unpaired *t*-test was performed to calculate statistical  
38  
39  
40  
41 significance ( $*P < 0.05$  vs control).  
42  
43  
44  
45  
46  
47

48 **Figure 3. Pemaifibrate but not bezafibrate attenuates VSMC proliferation.**

49  
50  
51 RASMCs were maintained in medium without FBS for 24 h. At 12 h before  
52  
53  
54 stimulation, control (DMSO), 1–1000 nM pemaifibrate (A), or 100–500  $\mu$ M  
55  
56  
57 bezafibrate and 100 nM pemaifibrate (B) were added, and cells were  
58  
59  
60

1  
2  
3 subsequently stimulated with 10% FBS. RASMCs were harvested, and cell  
4  
5  
6 proliferation was analyzed by cell counting using a hemocytometer. Data are the  
7  
8  
9 mean  $\pm$  SEM. One-way ANOVA was performed to calculate statistical  
10  
11  
12 significance (\*\* $P < 0.01$  vs control). RASMCs were maintained in medium without  
13  
14  
15 FBS for 24 h. At 12 h before stimulation, control (DMSO), 1–1000 nM pemafibrate  
16  
17  
18 (C), or 100–1000  $\mu$ M bezafibrate was added. After 48 h stimulation, cells were  
19  
20  
21 harvested, and BrdU assays were performed to measure DNA synthesis. Data  
22  
23  
24 are expressed as a relative absorbance to 0 nM pemafibrate. One-way ANOVA  
25  
26  
27 was performed to calculate statistical significance (\*\* $P < 0.01$  vs 0 nM).  
28  
29  
30

31  
32  
33  
34  
35 **Figure 4. Pemafibrate but not bezafibrate attenuates VSMC proliferation via**  
36  
37  
38 **PPAR alpha activation *in vitro*.**  
39  
40

41 RASMCs were transfected with negative control duplexes (control) or *PPAR*  
42  
43  
44 *alpha* siRNA (SiPPAR) and maintained in media supplemented with 10% FBS  
45  
46  
47 and control DMSO (D) or 100 nM pemafibrate (indicated as K) (A) and 100  $\mu$ M  
48  
49  
50 bezafibrate (indicated as B) (B). RASMCs were harvested, and cell proliferation  
51  
52  
53 was analyzed by cell counting using a hemocytometer. Data are the mean  $\pm$  SEM.  
54  
55  
56 One-way ANOVA was performed to calculate statistical significance (\*\* $P < 0.01$   
57  
58  
59  
60  
61  
62  
63  
64  
65

1  
2  
3 vs DMSO). (C) Quantitative real-time RT-PCR of *PPARalpha* was performed in  
4  
5  
6 RASMCs transfected with control siRNA (si-CT) or siRNA targeting *PPARalpha*  
7  
8  
9 (siPPARa). Gene expression was calculated by normalization to *HPRT*. An  
10  
11  
12 unpaired *t*-test was performed to calculate statistical significance (\*\**P* < 0.01 vs  
13  
14  
15 si-CT, n=3).  
16  
17  
18  
19  
20  
21

22 **Figure 5. Pemafibrate attenuates RASMC proliferation by reducing DNA**  
23  
24  
25 **synthesis but not by inducing apoptosis.**  
26  
27

1  
2  
3 10% FBS. After 24 h, cells were harvested, and western blotting of cyclin D1 was  
4  
5  
6 performed. Data are the mean  $\pm$  SEM. Two-way ANOVA was performed to  
7  
8  
9 calculate statistical significance. (\* $P$  < 0.05 vs RASMCs without pemaifibrate, n=3).

10  
11  
12 (D) Quantitative real-time RT-PCR of *Cyclin D1* was performed in RASMCs in the  
13  
14  
15 presence or absence of pemaifibrate. Gene expression was determined by  
16  
17  
18 normalization to *HPRT*. Two-way ANOVA was performed to calculate statistical  
19  
20  
21 significance (\* $P$  < 0.05, \*\* $P$  < 0.01 vs RASMCs without pemaifibrate, n=3).

22  
23  
24  
25  
26  
27  
28 **Figure 6. Pemaifibrate attenuates VSMC proliferation *in vivo*.**

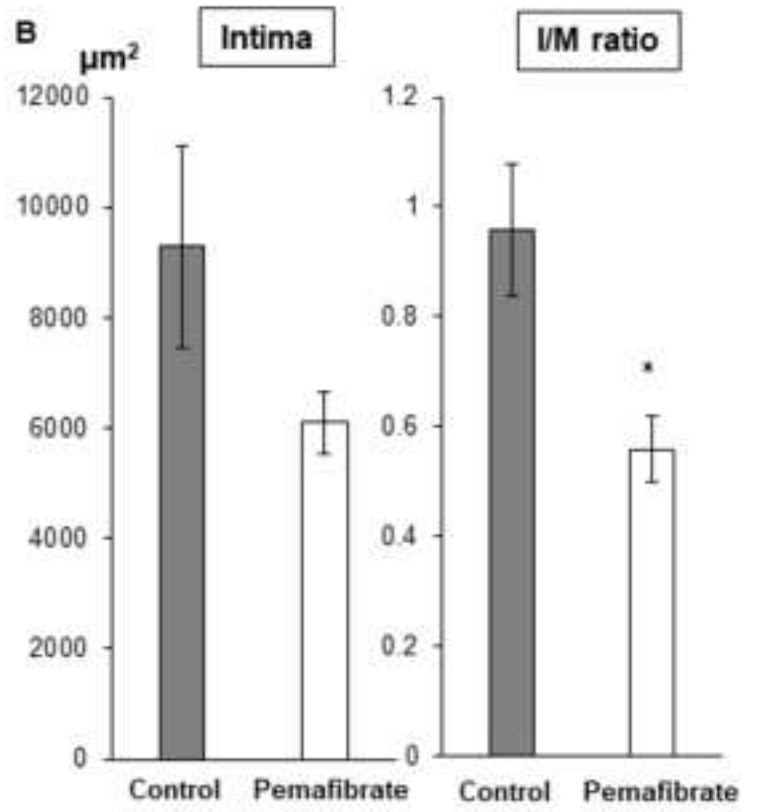

29  
30  
31  
32  
33 Endothelial denudation injuries were induced in the left femoral artery of mice  
34  
35  
36 maintained on normal chow (A, B) or a HFD (C, D). (A, C) Sections were  
37  
38  
39 subjected to immunohistochemistry for PCNA (red) and counterstained with DAPI  
40  
41  
42 to visualize nuclei (blue). Magnification, 630 $\times$ . (B, D) PCNA-positive cells were  
43  
44  
45 quantified by analyzing the fraction of stained cells to the total number of nuclei  
46  
47  
48 (n=5). Data are the mean  $\pm$  SEM. An unpaired *t*-test was performed to calculate  
49  
50  
51 statistical significance (\* $P$  < 0.05 vs control).

Table 1. Laboratory data of mice after treatment with or without pemafibrate.

	Normal chow		High-fat diet	
	Control( <i>n</i> =8)	Pemafibrate( <i>n</i> =6)	Control( <i>n</i> =9)	Pemafibrate( <i>n</i> =6)
Body weight (g)	25.0 ± 0.4	25.6 ± 0.3	35.3 ± 0.8 <sup>##</sup>	31.5 ± 0.7 <sup>*</sup>
Blood glucose (mg/dl)	176.2 ± 4.2	193.2 ± 5.3	182.4 ± 8.0	184.4 ± 9.0
Insulin (ng/ml)	0.49 ± 0.10	0.45 ± 0.08	1.21 ± 0.14 <sup>##</sup>	0.63 ± 0.10 <sup>*</sup>
FGF21 (ng/ml)	ND	ND	0.21 ± 0.04	1.31 ± 0.13 <sup>**</sup>
Triglyceride (mg/dl)	75.5 ± 12.3	42.0 ± 6.8 <sup>*</sup>	28.8 ± 2.9	13.6 ± 1.9 <sup>**</sup>
LDL cholesterol (mg/dl)	11.4 ± 0.4	19.4 ± 2.3 <sup>*</sup>	31.8 ± 3.9 <sup>##</sup>	53.8 ± 5.5
VLDL cholesterol (mg/dl)	6.3 ± 0.7	4.0 ± 0.4 <sup>*</sup>	2.5 ± 0.2 <sup>##</sup>	1.1 ± 0.3 <sup>**</sup>
HDL cholesterol (mg/dl)	77.6 ± 4.8	95.9 ± 3.4 <sup>*</sup>	115.3 ± 5.4 <sup>##</sup>	123.4 ± 3.8

One-way ANOVA was performed to calculate statistical significance (<sup>\*</sup>*P* < 0.05, <sup>\*\*</sup>*P* < 0.01 vs control, <sup>##</sup>*P* < 0.01 vs normal chow control).
